- 64 Filter apparatus.
- A multiwell filtration apparatus for the assay of microliter quantities is provided which prevents fluid loss by capillary action and gravity flow through a microporous membrane or ultrafilter. The filtration apparatus is particularly advantageous in assays requiring maintenance of fluid within the reaction wells for substantial time periods and in small sample volume assays in the range of 100 microliter volumes.

Filter Apparatus

10

15

1

The invention relates to laboratory apparatus useful in the assay ob biological and biochemical reactants and is particularly concerned with multiwell filtration devices able to retain fluids for substantial periods of time before filtration is performed.

multiplicity of individual wells or reaction chambers are commonly known laboratory tools. Such devices have been employed for a broad variety of purposes and assays as are exemplified by U.S. Patent Nos. 3,649,464; 4,304,865; 4,276,048; 4,154,795; and Re 30,562. Microporous membrane filters and filtration devices containing such microporous membranes have become especially useful with many of the recently developed cell and tissue culture techniques and assays - particularly those in the fields of virology and immunology.

30

35

Typically, a 96-well filtration plate is used to conduct multiple assays simultaneously some of which last several hours before filtration is actually performed. With such filtration plates, especially those containing microporous membranes, there is a well recognized and recurrent problem in that fluids in the wells tend to pass through the membrane by capillary action and gra-

vity flow thereby causing a loss of contents from within the reaction well before the desired stage in the experimental design. Prevention of fluid loss by capillary action and gravity flow becomes especially 5 important when living cells or tissues are being maintained or grown within the reaction wells. Under these circumstances, favorable media conditions for the cells or tissues must be maintained for hours or even days and any loss of fluid from the wells, however 10 small, will affect the condition of the cells and influence the results of the assay. Prevention of fluid loss through the membrane in this manner is also vitally important when the assay utilizes very small sample volumes as reactants, such test samples often being 15 less than 100 microliters in volume. The pendant drop that invariably forms on the underside of the microporous membrane due to such capillary action and gravity flow is typically about 50 microliters in volume and it is apparent that a fluid loss of such proportions must 20 drastically affect the assay.

Nevertheless, insofar as is presently known, no filtration apparatus has been able to prevent this loss of fluid from the reaction well, particularly under small sample volume assay conditions.

25

A filtration apparatus for the assay of microliter quantities of biological and biochemical reactants is provided comprising a plate having a plurality of apertures open at each and, filtration means disposed across and sealed about one end of each aperture thereby forming a well with a discrete filtering area and a hydrophobic fabric disposed across a bonded adjacent to the filtering area bounded by each well.

- The hydrophobic fabric prevents a loss of fluid by capillary action and gravity flow from within the well in the absence of an applied differential pressure.

 Additionally provided are fluid collection means and a guiding projection which directs such fluid as passes through the filtration means to a predetermined location within the fluid collection means.
- The present invention may be best understood when taken in conjunction with the accompanying drawing, in which:
 - Fig. 1 is an expanded view of a vacuum assembly usefulwith the invention;
 - Fig. 2 is an overhead view of a filtration apparatus comprising one embodiment of the present invention;
- Fig. 3 is a cross-sectional view of the preferred filtration apparatus comprising the present invention;

15

- Fig. 4 in one embodiment of fluid collections means useful with the preferred embodiment illustrated in Fig. 3; and
- Fig. 5 is another preferred embodiment of the invention illustrated in Fig. 3.
- The invention is an improvement in filtration apparatus having at least one reaction well which typically contains a microporous membrane for the separation and retention of matter from fluids. Attached adjacent to the microporous membrane is a porous hydrophobic fabric which is situated either above or preferably

below the filtering microporous membrane. This hydrophobic fabric prevents fluid loss by capillary action
and gravity flow through the membrane in the absence
of a vacuum force but will still allow diffusion of
gases into or out the interior of each well on the
plate.

Embodiments of the invention are most useful with the vacuum assembly shown in Fig. 1 which is capable of 10 simultaneously processing 96 individual test samples of up to 440 microliters (µ1) each. The vacuum assembly comprises a base 2 which acts as a vacuum chamber and contains a hose barb for connection to a regulated external vacuum source. Housed within the base 2 are 15 fluid collection means 4 which include a collection try 6 and/or a receiving plate 8 having up to 96 individual chambers for the collection of filtrate. A filter support 10 holding a 96-well filtration plate 12 lies above the fluid collection means 4 separated by 20 gaskets 14 and 16 which form an airtight seal in the presence of a vacuum force.

Detailed views of the filtration plate utilizing the preferred embodiment of the present invention are shown in Figs. 2 and 3. It will be appreciated that the number of wells found in the filtration plate are simply a matter of convenience for the investigator. The plate 20 may contain as few as one well or as many wells as are functionally permissible given the actual dimensions of the plate. The filtration plate may be formed of any resilient and nonreactive material commonly available, the composition of choise being a matter of convenience or economics only. Each well 22 comprises an aperture 24 through the entire depth of the plate, the thickness of the plate determining the

skilled in the art that the individual filtering areas 28 bounded by each well 22 can be removed via a filter punch after filtration for further processing if necessary.

As can be seen in Fig. 3, a hydrophobic fabric 30 is disposed across and bonded adjacent to the filtering areas 28 of the well 22. Preferably, the hydrophobic fabric is bonded to the filtration means abutting the well perimeter 32 such that a minute space 24 is created and maintained between the fabric 30 and the filtering area 28. The fabric 30 may be heat bondable or utilize and adhesive for attachment to the filtration means 26. In addition, the fabric 30 may be formed of woven or a nonwoven materials and be composed any of hydrophobic polyester, polyolefin, polytetrafluoroethylene or other polymer - many suitable varieties being commercially available.

10

15

20

25

It is preferred that attachment of the filtration means 26 and the hydrophobic fabric 30 to the plate 20 be performed as separate steps to insure their proper positioning and the formation of the minute space 34. Nevertheless, it is possible to attach both the filtrations means and the hydrophobic fabric simultaneously, particularly if a heat bondable hydrophobic material is used as the fabric layer.

Affixation of a porous hydrophobic fabric in this manner permits the use of small sample volumes, often less than 100 microliter (hereinafter µl), to be used as reactants. Without the fabric layer, a drop of fluid approximately 50 µl in volume will collect below the filtration means as a pendant drop and become lost. With the hydrophobic fabric in place, the pendant

drop that forms below the filtering area 28 as a result of capillary action and gravity flow will be substantially retained within minute space 34 and the tendency for liquid to pass through the filtering area is substantially reduced or entirely eliminated. As a result, assays during which the well contents require a fluid media incubation phase or a bathing of the reactants in fluid can be performed without errors or incon-

10

15

20

35

venience.

Another aspect of the present invention is the pendant drop release fixture illustrated in Figs. 3 and 5. This fixture is intended to be used with the multichambered fluid collection means shown in Figs. 1 and, 4 which is designed to receive filtrate from the interior of the well aligned directly above it via a plurality of individual receiving chambers 50. In this manner, the filtrate from each well will be retained separately. This compartmentalization feature alone, however, may not correct for the problem of comingling of filtrates deriving from different wells as the fluid is pulled through the hydrophobic fabric by an applied differential pressure. Similary, in those situations where the hydrophobic fabric is not present or is not necessary for the purposes of the assay, pendant drops will form and routinely collect on the underside of each filtering area, In small volume assays, the worker cannot afford to lose the 50 µl hanging as a drop from the membrane. Even in larger volume assays, an accidental movement or subsequent manipulations of the filter plate will dislodge the pendant drop and cause it to fall into the wrong receiving chamber causing cross-contamination of filtrates and erroneous test results.

. 1 Both these kinds of problems are corrected by placement of a pendant drop release fixture - in the form of a guiding projection 60 - between the filtering area 28 and the fluid collection means 4 beneath the plate 2o. 5 The preferred embodiment of this guiding projection 60 appears in Figs. 3 and 5 as a series of spikes 60 molded in a pattern corresponding to the individual filtering areas 28 in the plate 20. Each spike 60 serves a dual function: first, as a surface upon which the 10 small volumes of fluid which would otherwise be lost as a pendant drop are collected and removed from the filtering area 28; second, as a guide by which the fluids forming a pendant drop are directed to the appropriate chamber 50 in the fluid collection means 4. The pro-15 jections 60 can be injection molded or a die cut assembly. Any molding polymer material such as nylon, polystyrene, polycarbonate and polyethylene may be used for making the guiding projections; however, a hydrophilic material is preferred because it promotes interception 20 and guidance of the pendant drop.

It is expected that the hydrophobic fabric and the fluid guiding projection will be used in tandem in the majority of assays. Nevertheless, where retention of fluid within the well is not necessary, the pendant drop release fixture may be used alone to advantage.

1

1. A filtration apparatus comprising: a plate having at least one aperture open at each end;

filtration means disposed over one end of said aperture in said plate such that a well having a discrete filtering area is formed; and a hydrophobic fabric attached to said filtration means adjacent to said filtering area.

20

2. A filtration apparatus comprising: a plate having at least one aperture open at each end;

filtration means disposed over across one end of
said aperture in said plate such that a well having
a discrete filtering area is formed; and
a projection aligned beneath said filtration means
such that fluid passing through said filtering
area is directed to a predetermined location.

30

3. A filtration apparatus comprising: a plate having at least one aperture open at each end; filtration means disposed over one end of said

aperture such that a well having a discrete filtering

- area is formed;
 a hydrophobic fabric attached to said filtration
 means adjacent to said filtering area; and
 a projection aligned beneath said filtration means
 such that fluid passing through said filtering area
 is directed to a predetermined location.
- 4. The filtration apparatus as recited in claim 1, 2 or 3 wherein said filtration means includes a microporous membrane.
 - 5. The filtration apparatus as recited in claim 4 wherein said filtration means includes a microporous membrane having a porosity of at least 25 manometers.

15

- 6. The filter apparatus as recited in claim 1, 2 or 3 wherein said filtration means includes ultrafiltration media.
- 7. The filtration apparatus as recited in claim 1 or 3 wherein said hydrophobic fabric is selected from the group consisting of woven or nonwoven polymers.
- 8. The filter apparatus as recited in claim 1 or 3 wherein said hydrophobic fabric is selected from the group consisting of polyesters, polyolefins and polytetrafluoroethylene.
- 9. The filter apparatus as recited in claim 1 or 3
 wherein said hydrophobic fabric is heat bondable.
 - 10. The filter apparatus as recited in claim 1 or 3 wherein said hydrophobic fabric is attached with

1 adhesive.

- 11. The filtration apparatus as recited in claim 1, 2 or 3 further comprising fluid collections means disposed beneath said filtration means.
- 12. The filtration apparatus as recited in claim 11 wherein said fluid collection means includes a plurality of individual receiving chambers.

13. The filtration apparatus as recited in claim 2 or 3 wherein said projection is disposed upon fluid collection means.
